

Graphs: Finding shortest paths

Tecniche di Programmazione – A.A. 2020/2021

What is the shortest path between s and v?

Summary

- Definitions
- Floyd-Warshall algorithm
- ▶ Bellman-Ford-Moore algorithm
- Dijkstra algorithm

Definitions

Graphs: Finding shortest paths

Definition: weight of a path

- ▶ Consider a directed, weighted graph G=(V, E), with weight function $w: E \rightarrow \mathbb{R}$
 - This is the general case: undirected or un-weighted are automatically included
- The weight w(p) of a path p is the sum of the weights of the edges composing the path

$$w(p) = \sum_{(u,v)\in p} w(u,v)$$

Definition: shortest path

- The shortest path between vertex *u* and vertex *v* is defined as the mininum-weight path between *u* and *v*, if the path exists.
- ▶ The weight of the shortest path is represented as $\delta(u,v)$
- If v is not reachable from u, then (by definition) $\delta(u,v)=\infty$

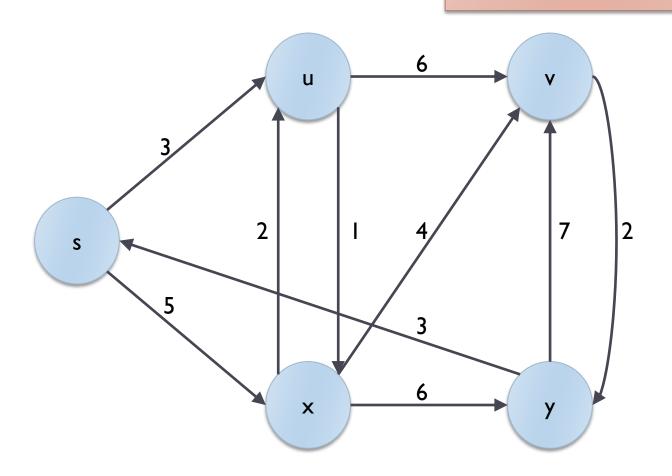

Finding shortest paths

- Single-source shortest path (SS-SP)
 - Given *u* and *v*, find the shortest path between *u* and *v*
 - Given *u*, find the shortest path between *u* and any other vertex
- All-pairs shortest path (AP-SP)
 - Given a graph, find the shortest path between any pair of vertices

What to find?

- Depending on the problem, you might want:
 - ▶ The **value** of the shortest path weight
 - Just a real number
 - The actual path having such minimum weight
 - For simple graphs, a sequence of vertices.
 - For multigraphs, a sequence of edges

What is the shortest path between s and v?

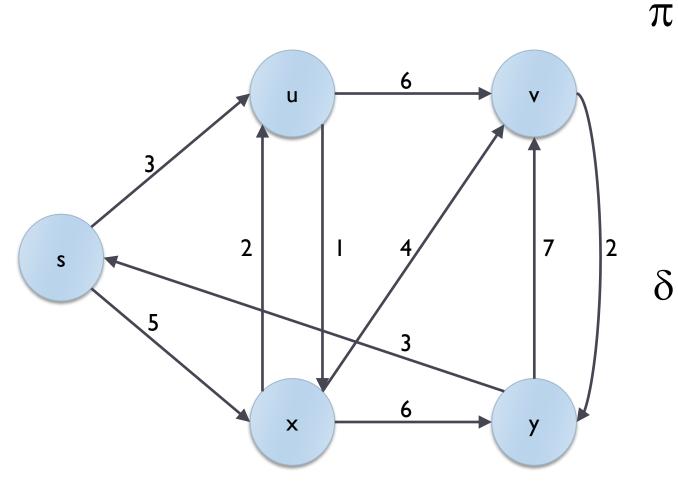

Representing shortest paths

- To store all shortest paths from a single source u, we may add
 - For each vertex v, the **weight** of the shortest path $\delta(u,v)$
 - For each vertex v, the "**preceding**" vertex $\pi(v)$ that allows to reach v in the shortest path
 - For multigraphs, we need the preceding edge

Example:

- Source vertex: u
- For any vertex *v*:
 - b double v.weight;
 - Vertex v.preceding;

Vertex	Previous
S	NULL
u	S
x	u
٧	X
у	٧

Vertex	Weight
S	0
u	3
x	4
٧	8
у	10

The "previous" vertex in an intermediate node of a minimum path does not depend on the final destination

Example:

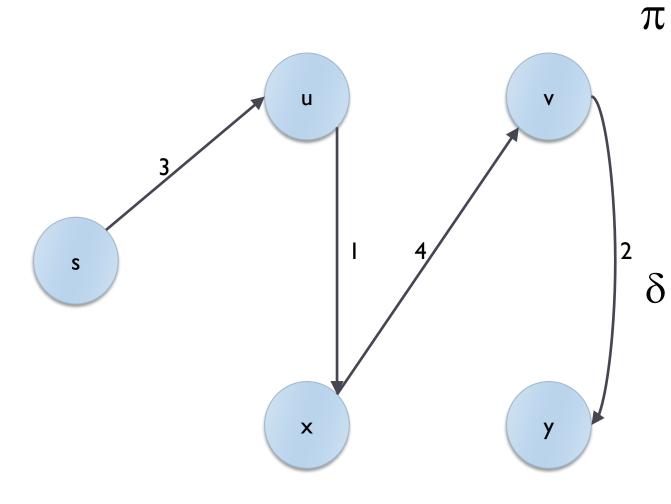

- Let p_1 = shortest path between u and v_1
- Let p_2 = shortest path between u and v_2
- ▶ Consider a vertex $w \in p_1 \cap p_2$
- The value of $\pi(w)$ may be chosen in a single way and still guarantee that both p_1 and p_2 are shortest

Shortest path graph

- Consider a source node u
- Compute all shortest paths from u
- ▶ Consider the relation $E\pi = \{ (v.preceding, v) \}$
- ► Eπ ⊂ E
- ▶ $\forall \pi = \{ v \in V : v \text{ reachable from } u \}$
- $G\pi = G(V\pi, E\pi)$ is a subgraph of G(V,E)
- $G\pi$: the predecessor-subgraph

Shortest path tree

- $G\pi$ is a tree (due to the Lemma) rooted in u
- In $G\pi$, the (unique) paths starting from u are always shortest paths
- $G\pi$ is not unique, but all possible $G\pi$ are equivalent (same weight for every shortest path)

Vertex	Previous
S	NULL
u	S
×	u
٧	X
у	٧

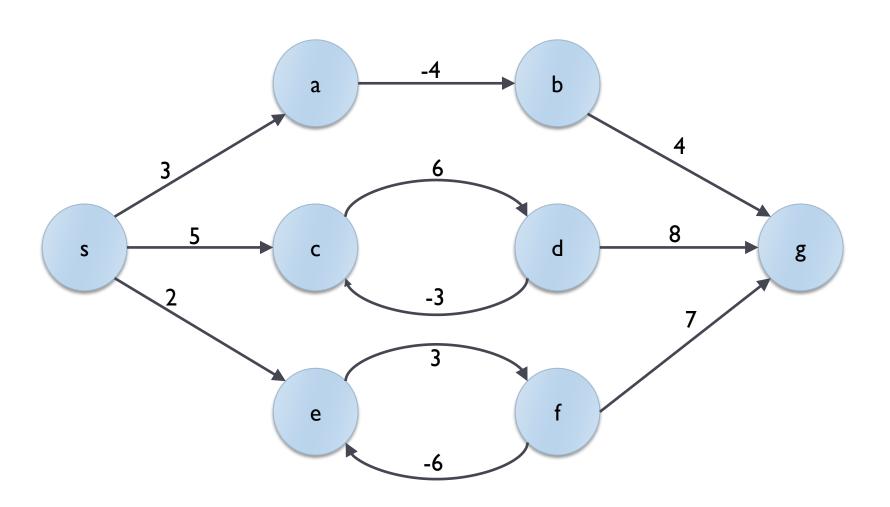

Vertex	Weight
S	0
u	3
X	4
٧	8
у	10

Special case

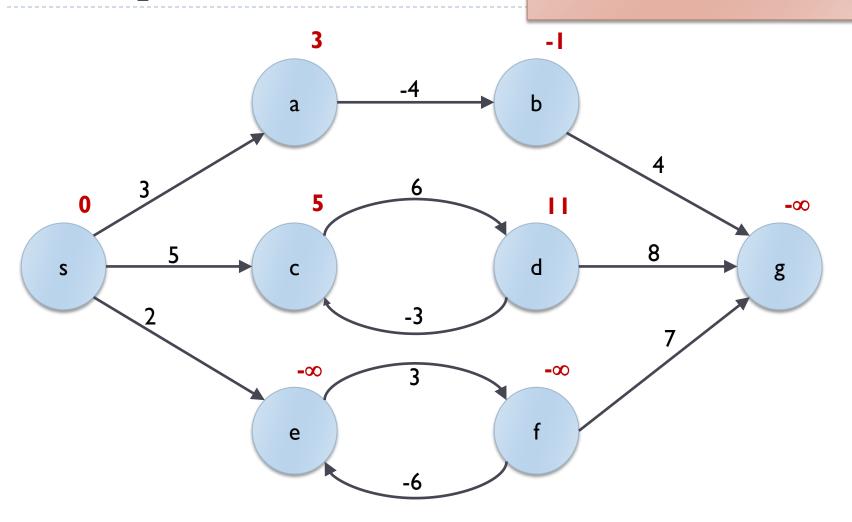

If G is an un-weighted graph, then the shortest paths may be computed just with a breadth-first visit

Negative-weight cycles

- Minimum paths cannot be defined if there are negativeweight cycles in the graph
- In this case, the minimum path does not exist, because you may always decrease the path weight by going once more through the loop.
- ▶ Conventionally, in these case we say that the path weight is $-\infty$.

Minimum-weight paths from source vertex s

- ▶ Consider an ordered weighted graph G=(V,E), with weight function $w: E \rightarrow \mathbb{R}$.
- Let $p=\langle v_1, v_2, ..., v_k \rangle$ a shortest path from vertex v_1 to vertex v_k .
- For all i,j such that $1 \le i \le j \le k$, let $p_{ij} = \langle v_i, v_{i+1}, ..., v_j \rangle$ be the sub-path of p, from vertex v_i to vertex v_j .
- ▶ Therefore, p_{ij} is a shortest path from v_i to v_j .

Corollary

- Let p be a shortest path from s to v
- ▶ Consider the vertex u, such that (u,v) is the last edge in the shortest path
- ▶ We may decompose p (from s to v) into:
 - A sub-path from s to u
 - ightharpoonup The final edge (u,v)
- Therefore

 $\delta(s,v) = \delta(s,u) + w(u,v)$

If we arbitrarily chose the vertex u, then for all edges $(u',v) \in E$ we may say that

 $\delta(s,v) \leq \delta(s,u') + w(u',v)$

Relaxation

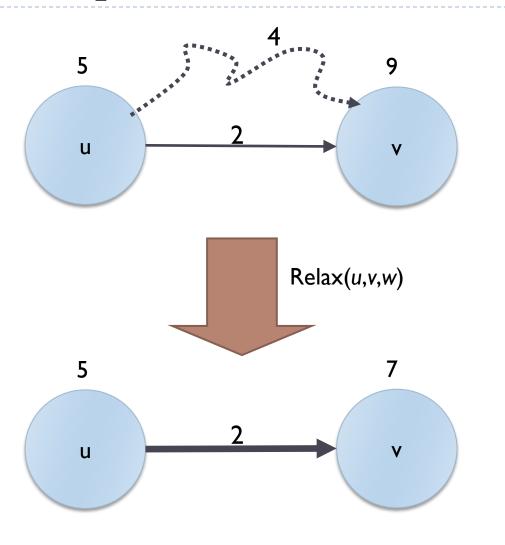

- Most shortest-path algorithms are based on the relaxation technique
- It consists of
 - Vector d[u] represents $\delta(s,u)$
 - \blacktriangleright Keeping track of an updated estimate d[u] of the shortest path towards each node u
 - Relaxing (i.e., updating) d[v] (and therefore the predecessor $\pi[v]$) whenever we discover that node v is more conveniently reached by traversing edge (u,v)

Initial state

- Initialize-Single-Source(G(V,E), s)
 - 1. **for** all vertices $v \in V$
 - 2. **do**
 - $d[v] \leftarrow \infty$
 - 2. $\pi[v] \leftarrow NIL$
 - 3. $d[s] \leftarrow 0$

Relaxation

- We consider an edge (u,v) with weight w
- ▶ Relax(*u*, *v*, *w*)
 - i. if d[v] > d[u] + w(u,v)
 - 2. then
 - $d[v] \leftarrow d[u] + w(u,v)$
 - 2. $\pi[v] \leftarrow u$

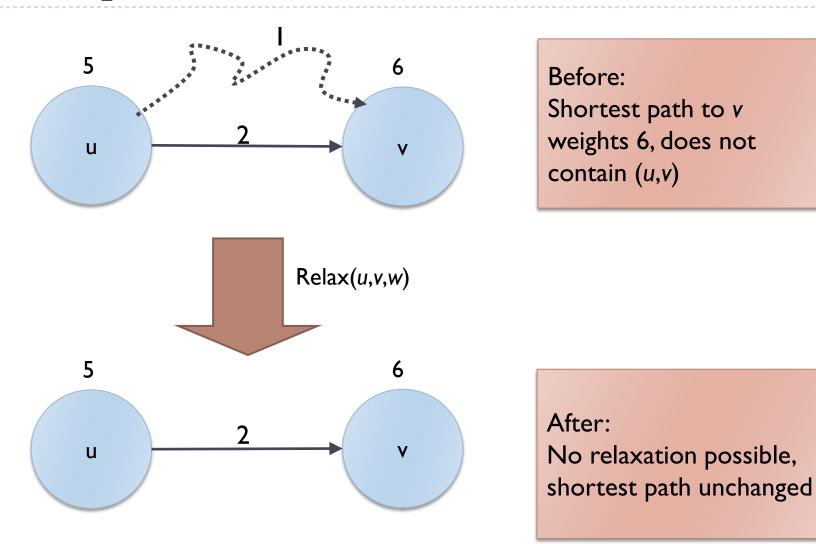

Before:

Shortest known path to v weights 9, does not contain (u,v)

After:

Shortest path to v weights 7, the path includes (u,v)

- ▶ Consider an ordered weighted graph G=(V, E), with weight function $w: E \rightarrow \mathbb{R}$.
- Let (u,v) be an edge in G.
- ▶ After relaxation of (u,v) we may write that:
 - \rightarrow d[v] \leq d[u]+w(u,v)

▶ Consider an ordered weighted graph G=(V, E), with weight function w: $E \rightarrow \mathbb{R}$ and source vertex $s \in V$. Assume that G has no negative-weight cycles reachable from s.

Therefore

- After calling Initialize-Single-Source(G,s), the predecessor subgraph $G\pi$ is a rooted tree, with s as the root.
- Any relaxation we may apply to the graph does not invalidate this property.

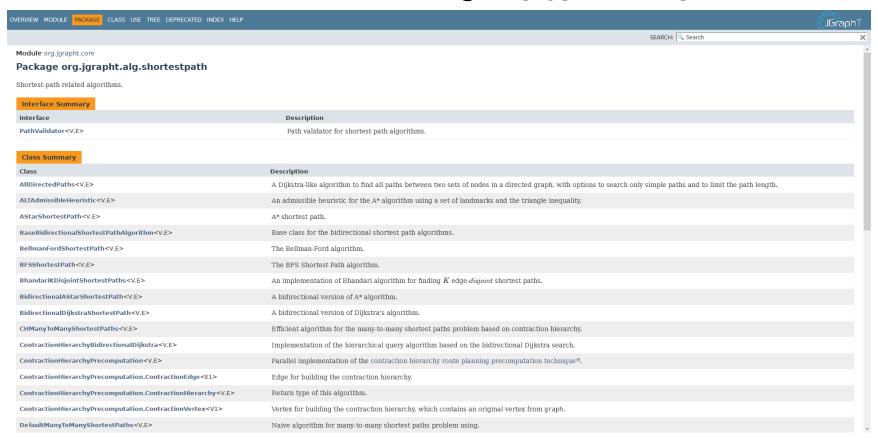

- Given the previous definitions.
- Apply any possible sequence of relaxation operations
- ▶ Therefore, for each vertex v
 - ▶ $d[v] \ge \delta(s,v)$
- Additionally, if $d[v] = \delta(s,v)$, then the value of d[v] will not change anymore due to relaxation operations.

Shortest path algorithms

- Various algorithms
- Differ according to one-source or all-sources requirement
- Adopt repeated relaxation operations
- Vary in the order of relaxation operations they perform
- May be applicable (or not) to graph with negative edges (but no negative cycles)

Implementations

Package org.jgrapht.alg.shortestpath

...and many more

https://jgrapht.org/javadoc/org.jgrapht.core/org/jgrapht/alg/shortestpath/package-summary.html

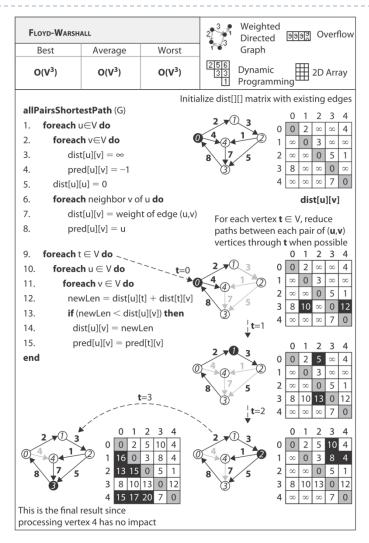

Floyd-Warshall algorithm

Graphs: Finding shortest paths

Floyd-Warshall algorithm

- Computes the all-source shortest path (AP-SP)
- dist[i][j] is an n-by-n matrix that contains the length of a shortest path from vi to vj.
- if dist[u][v] is ∞, there is no path from u to v
- pred[s][j] is used to reconstruct an actual shortest path: stores the predecessor vertex for reaching vj starting from source vs

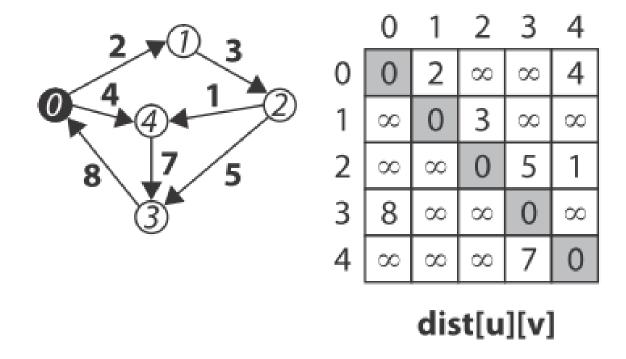

Floyd-Warshall: initialization

allPairsShortestPath (G)

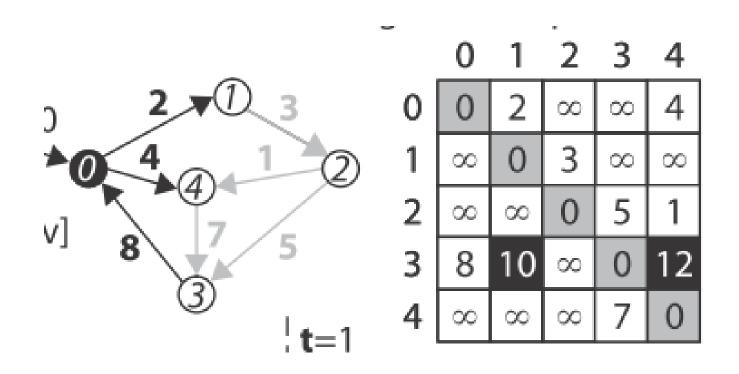

- foreach u∈V do
- foreach v∈V do
- 3. $\operatorname{dist}[u][v] = \infty$
- 4. pred[u][v] = -1
- 5. dist[u][u] = 0
- 6. **foreach** neighbor v of u **do**
- 7. dist[u][v] = weight of edge (u,v)
- 8. pred[u][v] = u

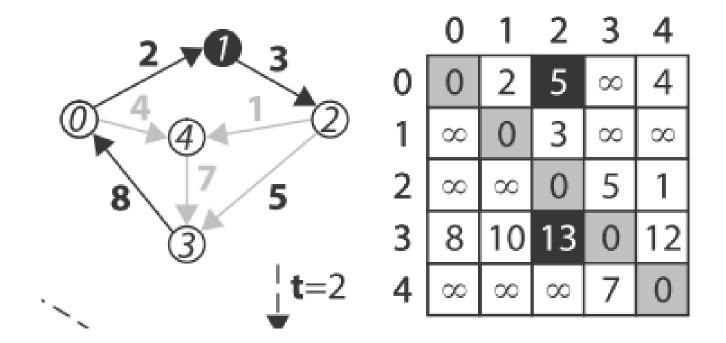

Example, after initialization

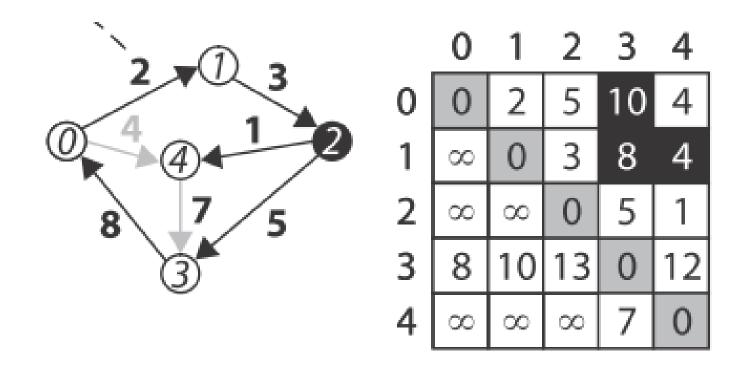

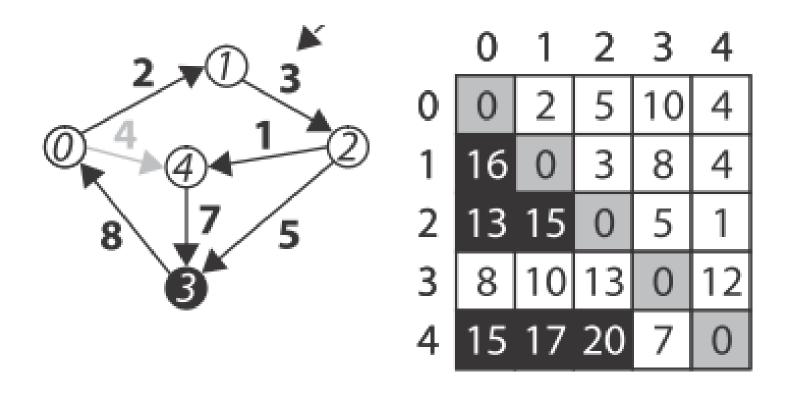

Floyd-Warshall: relaxation

```
\textbf{for each } t \in V \textbf{ do } \llcorner_{\scriptscriptstyle \diagdown}
         foreach u \in V do
10.
             foreach v \in V do
11.
12.
              newLen = dist[u][t] + dist[t][v]
13.
              if (newLen < dist[u][v]) then
14.
                dist[u][v] = newLen
                pred[u][v] = pred[t][v]
15.
```

Complexity

- The Floyd-Warshall is basically executing 3 nested loops,
 each iterating over all vertices in the graph
- Complexity: O(V³)

Implementation

Bellman-Ford-Moore Algorithm

Graphs: Finding shortest paths

Bellman-Ford-Moore Algorithm

- Solution to the single-source shortest path (SS-SP) problem in graph theory
- Based on relaxation (for every vertex, relax all possible edges)
- Does not work in presence of negative cycles
 - but it is able to detect the problem
- ► O(V·E)

Bellman-Ford-Moore Algorithm

```
dist[s] \leftarrow o
                       (distance to source vertex is zero)
for all v \in V - \{s\}
    do dist[v] \leftarrow \infty (set all other distances to infinity)
for i \leftarrow o to |V|
    for all (u, v) \in E
        do if dist[v] > dist[u] + w(u, v) (if new shortest path found)
              then d[v] \leftarrow d[u] + w(u, v) (set new value of shortest path)
                        (if desired, add traceback code)
for all (u, v) \in E (sanity check)
        do if dist[v] > dist[u] + w(u, v)
              then PANIC!
```

Dijkstra's Algorithm

Graphs: Finding shortest paths

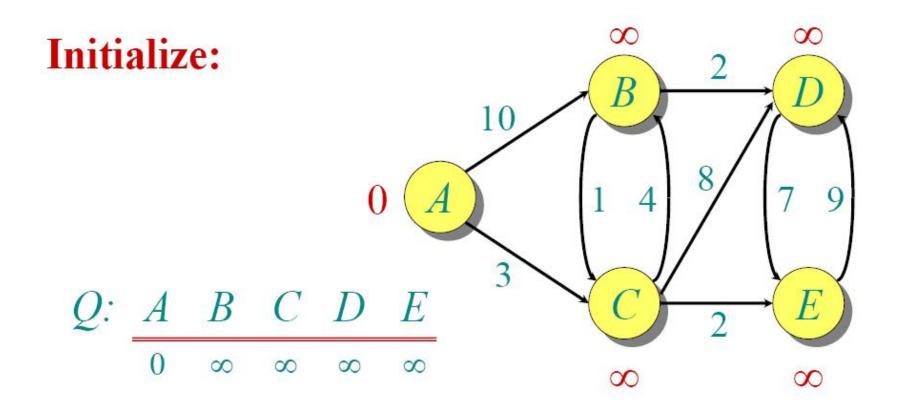

Dijkstra's algorithm

- Solution to the single-source shortest path (SS-SP) problem in graph theory
- Works on both directed and undirected graphs
- All edges must have nonnegative weights
 - the algorithm would miserably fail
- Greedy
 - ... but guarantees the optimum!

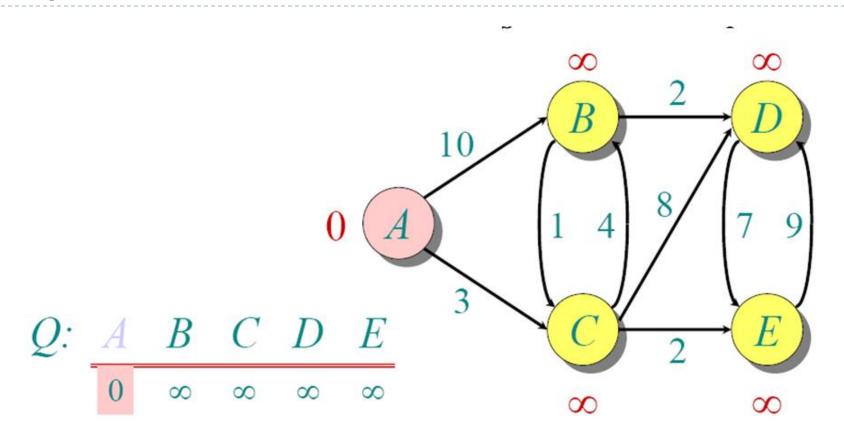

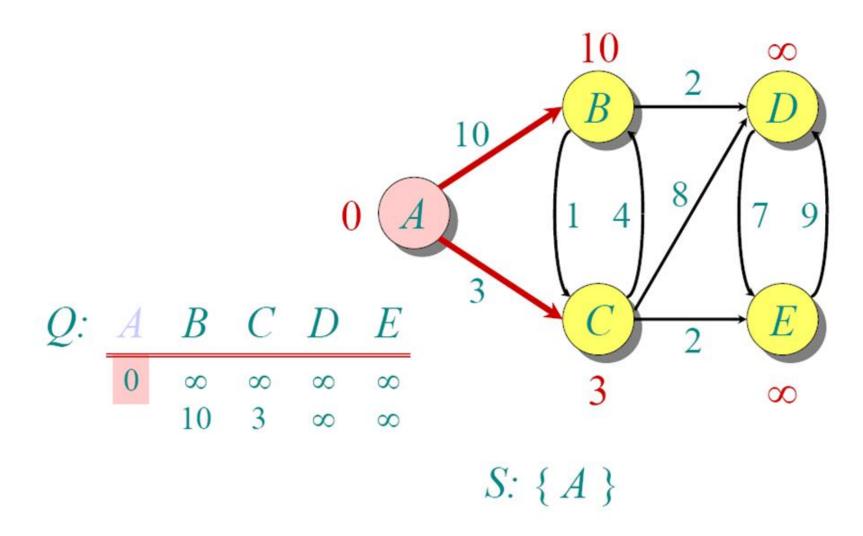

Dijkstra's algorithm

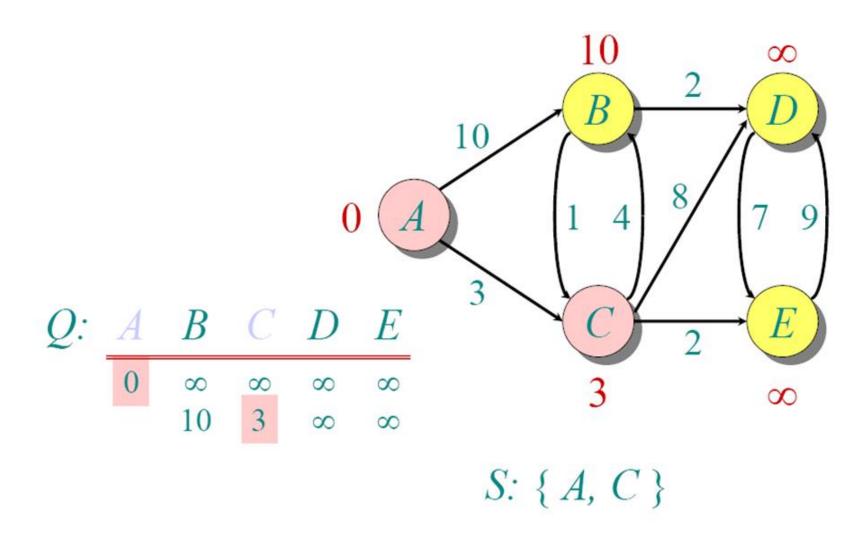

```
dist[s] \leftarrow o
                       (distance to source vertex is zero)
for all v \in V - \{s\}
    do dist[v] \leftarrow \infty (set all other distances to infinity)
                    (S, the set of visited vertices is initially empty)
S←Ø
                       (Q, the queue initially contains all vertices)
O←V
                       (while the queue is not empty)
while Q ≠Ø
do u \leftarrow mindistance(Q,dist) (select e \in Q with the min. distance)
                                   (add u to list of visited vertices)
   S \leftarrow S \cup \{u\}
   for all v \in neighbors[u]
        do if dist[v] > dist[u] + w(u, v) (if new shortest path found)
              then d[v] \leftarrow d[u] + w(u, v) (set new value of shortest path)
                       (if desired, add traceback code)
```

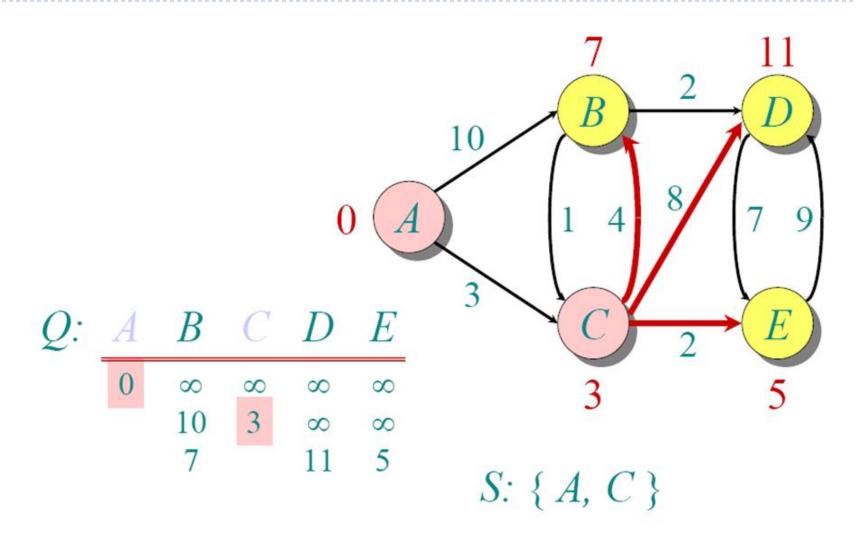

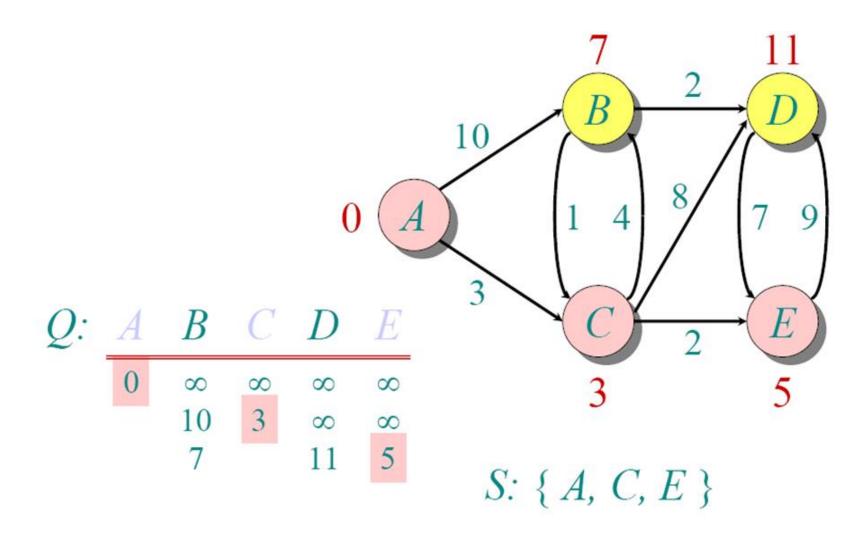

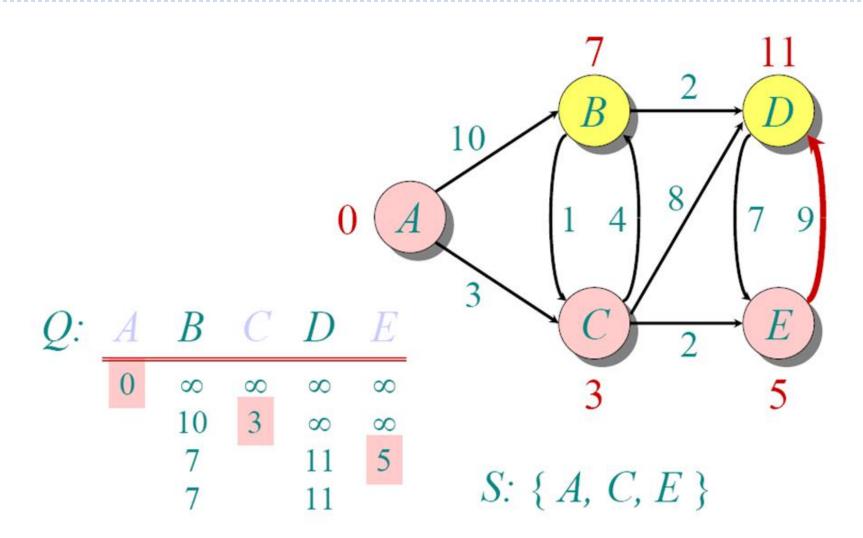

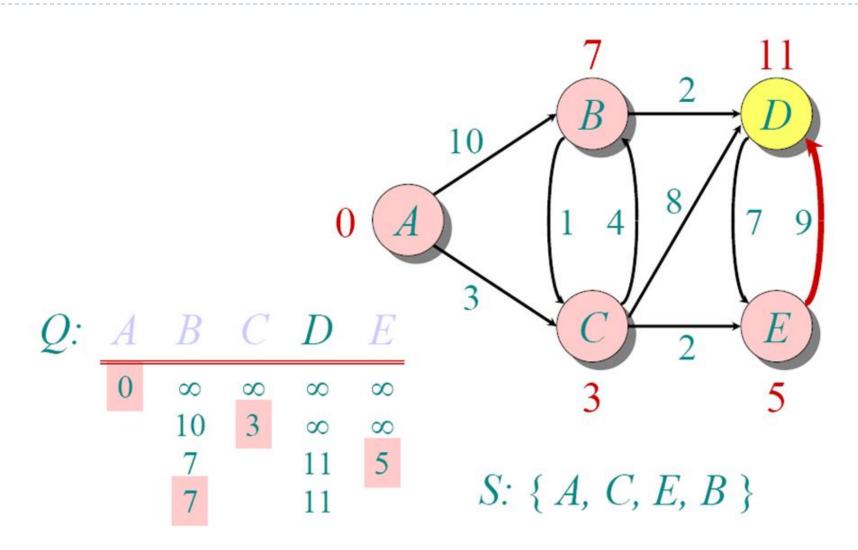

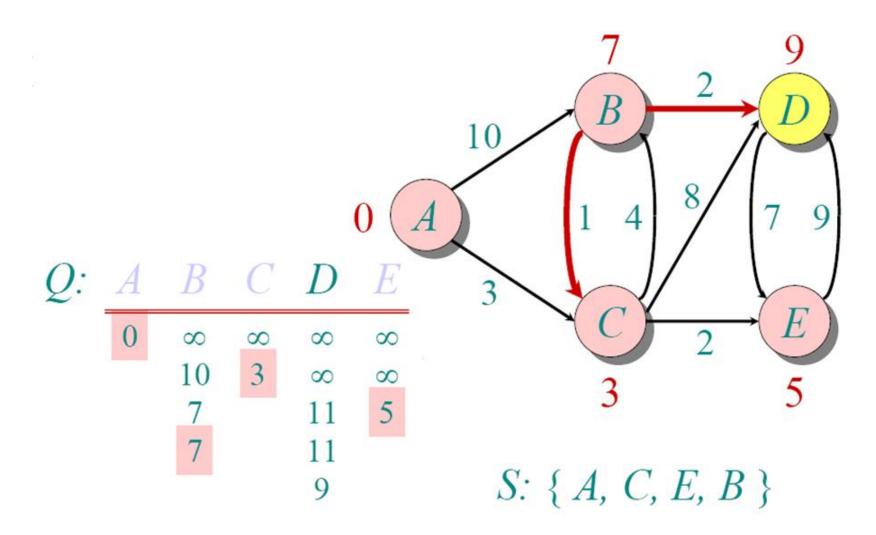

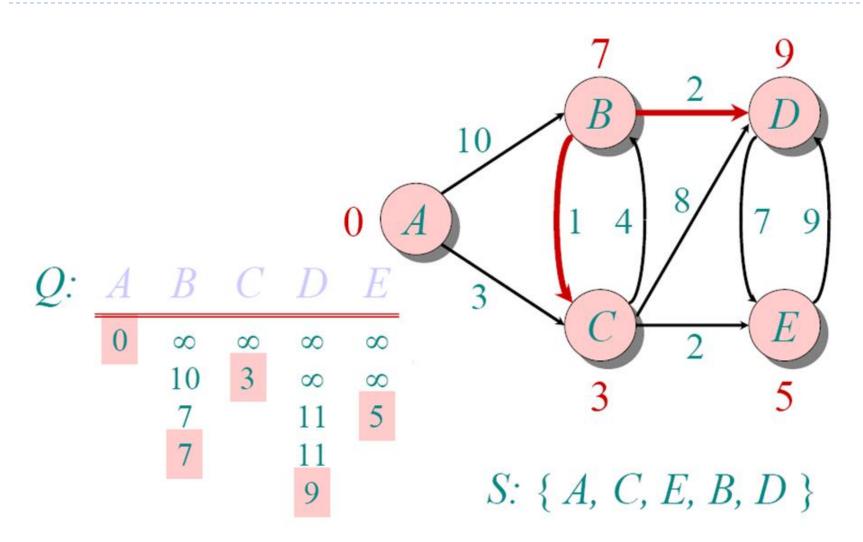

Dijkstra efficiency

▶ The simplest implementation is:

$$O(E + V^2)$$

▶ But it can be implemented more efficently:

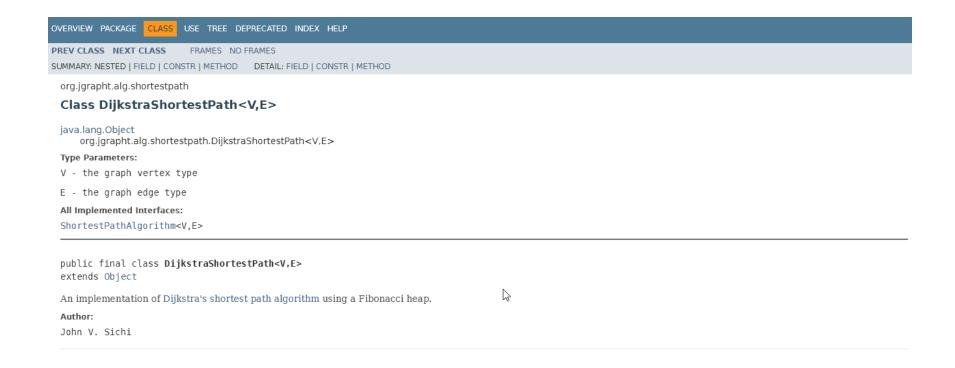

$$O(E + V \cdot \log V)$$

Floyd-Warshall: O(V³)

Bellman-Ford-Moore : O(V·E)

Implementation

Shortest Paths wrap-up

Algorithm	Problem	Efficiency	Limitation
Floyd-Warshall	AP	$O(V^3)$	No negative cycles
Bellman-Ford	SS	$O(V \cdot E)$	No negative cycles
Repeated Bellman-Ford	AP	$O(V^2 \cdot E)$	No negative cycles
Dijkstra	SS	$O(E + V \cdot \log V)$	No negative edges
Repeated Dijkstra	AP	$O(V \cdot E + V^2 \cdot \log V)$	No negative edges
Breadth-First visit	SS	O(V+E)	Unweighted graph

```
public class FloydWarshallShortestPaths<V,E>
public class BellmanFordShortestPath<V,E>
public class DijkstraShortestPath<V,E>
```

```
// APSP
List<GraphPath<V,E>> getShortestPaths(V v)
GraphPath<V,E> getShortestPath(V a, V b)

// SSSP
GraphPath<V,E> getPath()
```
